1 Question 1

Chebyshev approximation using equidistant nodes and Chebyshev nodes. However, there is a difference between lecture slides 7 and the notes from te lecture, as you will see in the code:

```
function [yequi,ychebsli,ycheblec] = cheb(fct,x,m,xmin,
      xmax)
   % In Miranda-Fackler, in fundefn, n is the degree of
      approximation, which
   \% is the number of nodes (m) -1. However, there is a
      problem with 2 nodes,
   % so this is also set to 2 and is kept in mind.
   c = max(m-1,2);
6
   %define function space with fundefn
  fspace=fundefn('cheb',c,xmin,xmax);
   distance=(xmax-xmin)/(m-1);
   nodesequi=zeros(m,1);
11
   ynodesequi=zeros(m,1);
12
   nodeschebslides=zeros(m,1);
   ynodeschebsli=zeros(m,1);
   ynodescheblec=zeros(m,1);
   nodescheblecture=zeros(m,1);
   %create nodes
   %also, calculate function values at x
17
18
   for j=1:m
19
     nodesequi(j)=xmin+(j-1)*distance;
                                                    %
        equidistant nodes
20
     ynodesequi(j)=fct(nodesequi(j));
                                                    %
        function values
     nodeschebslides(j)=-cos((2*j-1)*pi/(2*m));
                                                     %
        Chebyshev nodes according to slide set 7
22
     nodescheblecture(j)=-cos((2*j-1)*pi/(m));
        Chebyshev nodes according to lecture notes
23
     ynodeschebsli(j)=fct(nodeschebslides(j));
```

```
ynodescheblec(j)=fct(nodescheblecture(j));
24
25
  end
26
27 | % calculate the matrix of basis functions
  Bchebsli=funbas(fspace, nodeschebslides); %Chebyshev
  Bcheblec=funbas(fspace, nodescheblecture); %Chebyshev
32
  %get polynomial coefficients
  cequi=Bequi\ynodesequi; %equidistant
  cchebsli=Bchebsli\ynodeschebsli; %chebychev
36
  ccheblec=Bcheblec\ynodescheblec;
37
38
  %approximate the function
39
   yequi=funeval(cequi,fspace,x);
  ychebsli=funeval(cchebsli,fspace,x);
41
  ycheblec=funeval(ccheblec,fspace,x);
42
43
  end
```

Linear and cubic splines, also using the Miranda-Fackler toolbox:

```
function [yspllin,ysplcub]=spl(fct,x,m,xmin,xmax)
  | % In Miranda-Fackler, in fundefn, n is the degree of
      approximation, which
3
   % is the number of nodes (m) -1
4
5
     fspacespllin=fundefn('spli',m-1,xmin,xmax,1);
        linear splines
6
     fspacesplcub=fundefn('spli',m-1,xmin,xmax,3);
        cubic splines
     distance=(xmax-xmin)/(m-1);
8
     nodesspl=zeros(m,1);
9
     ynodes=zeros(m,1);
     %nodes
11
     for i=1:m
12
       nodesspl(i)=xmin+(i-1)*distance;
                                           %eqidistant
          nodes
                                           %fct values at
       ynodes(i)=fct(nodesspl(i));
          nodes
14
     end
15
16
     %calculate the matrix of basis functions
17
     Bspllin=funbas(fspacespllin,nodesspl);
18
     Bsplcub=funbas(fspacesplcub, nodesspl);
```

```
19
20
     %get polynomial coefficients
21
     cspllin=Bspllin\ynodes;
22
     csplcub=Bsplcub\ynodes;
23
24
     %approximate the function
25
     yspllin=funeval(cspllin,fspacespllin,x);
26
     ysplcub=funeval(csplcub,fspacesplcub,x);
27
28
  end
```

The function, which was given in the task, defined for potential vector input:

```
1 function y=simplef(x)
2 y=1/(1+25.*x.^2);
end
```

Main code for PS4P1:

```

Plots are ordered in chronological order! (For comparison, the residuals to actual function are plotted.)

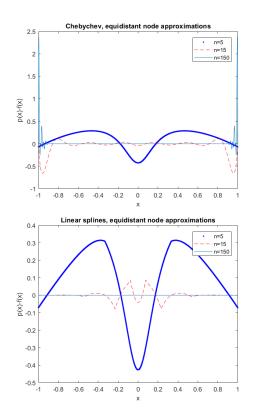

For n=5, equidistant nodes and Chebyshev nodes as well as linear splines are very similar. For n=15, linear splines become more edgy. It performs well at the edges and average else. Both Chebyshev approximations are very similar in [-0.75;0.75], while equidistant nodes fall off at the edges (as expected). For n=150 this effect is even stronger, but it moves closer to the corner. The others are not comparable due to the residual scale. The effect does not occur when using Chebyshev nodes because there are more nodes at the corner to prevent these large fluctuations.

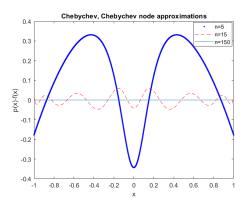

In this figure again the effect of equidistant nodes when using Chebyshev can be seen as large fluctuations at the corner. Besides this, as the number of nodes increases, the approximation gets closer to the real function.

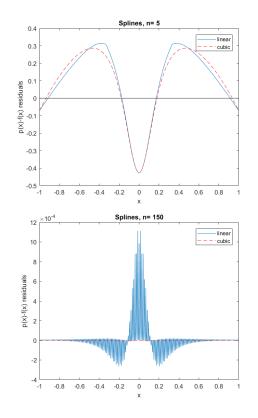

Linear and cubic splines are very similar when n=5. For n=15 one can observe that cubic splines are smoother than linear splines and perform better in the center (around 0), whereas linear splines perform better at the corner (it becomes smooth and then becomes nearly a straight line). For n=150, at first sight, linear splines perform badly, but it is only relative to cubic splines (look at the scale). As n increases, the approximation gets better when using splines.

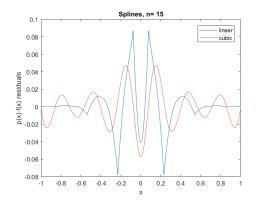

The slides formula seems to be the right one. The function is symmetric and so is the approximation. The lecture formula leads to very odd (i.e. asymmetric) approximations.

In general, it seems to be very odd that the residuals at 0 are not 0, because there should be a node and thus the residual should be zero. Maybe it is due to the toolbox calculations. Other possibilities have been thought of and precluded.

2 Question 2

The first order condition of the unconstrained maximisation problem is given by

$$u'(C_0) - \mathbb{E}u'(W_0(1+r) - C_0) = 0$$

Accordingly, the optimal consumption plan obeys the Euler equation

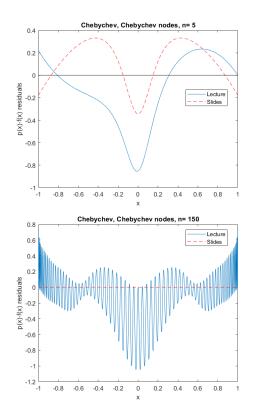

$$u'(C_0) = \mathbb{E}u'(C_1)$$
 (Euler EQ)

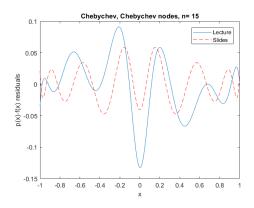

Quadratic utility Let the utility function be quadratic. Then, marginal utility is given by

$$u'(C_t) = -(C_t - \bar{C}) = \bar{C} - C_t$$
 (Marginal utility)

Moreover,

$$u''(C_t) = -1 < 0$$
 (Risk aversion)
 $u'''(C_t) = 0$ (Prudence)

In order to obtain the optimal consumption, plug the marginal utility into the Euler equation

$$\bar{C} - C_0 = \mathbb{E}(\bar{C} - C_1)$$

$$\bar{C} - C_0 = \mathbb{E}(\bar{C} - (W_0(1+r) - C_0))$$

$$2C_0 = W_0\mathbb{E}(1+r)$$

$$C_0 = \frac{1}{2}W_0\mathbb{E}(1+r)$$

Note that marginal utility is linear in C_t . Consequently, we could exploit linearity of the expectation operator which yields more generally

$$\mathbb{E}(u'(C_t)) = u'(\mathbb{E}(C_t))$$

This is why certainty equivalence holds, i.e., the intertemporal consumption decision remains unchanged when agents are exposed to more or even less uncertainty. Indeed, expected lifetime utility is reduced by income risks (concave utility). However, the comparative statics require to look at the third derivative which indicates that agents are not influenced by the degree of income uncertainty. In case of linear marginal utility agents are not prudent. It is quite hard

to judge whether this result makes economic sense, i.e., such a function provides a meaningful utility representation. There is a lot of empirical work on the willingness to insure, it is true, but prudence is a different issue. If we believe in the precautionary savings motive (which makes intuitively sense), quadratic utility is inappropriate.

CRRA utility In case of CRRA utility the three derivatives are given by

$$u'(C_t) = C_t^{-\gamma}$$
 for any $\gamma \neq 1$ (Marginal utility)
 $u''(C_t) = -\gamma C_t^{-(\gamma+1)} < 0$ (Risk aversion)
 $u'''(C_t) = \gamma (1+\gamma) C_t^{-(\gamma+2)} > 0$ (Prudence)

The last two derivatives tell us that marginal utility is strictly convex. Therefore, the agent is prudent. If agents are exposed to higher income uncertainty (i.e., higher variance in r) precautionary savings reduce present consumption. These savings allow them to prepare for the possibility of more severe income states.

Apparently, $\mathbb{E}(u'(C_t)) = u'(\mathbb{E}(C_t))$ will no longer hold. In order to derive the optimal consumption, plug the first derivative into the Euler equation:

$$C_0^{-\gamma} = \mathbb{E}(C_1^{-\gamma})$$

$$= \mathbb{E}((W_0(1+r) - C_0)^{-\gamma})$$

$$\Rightarrow C_0 = \mathbb{E}[(W_0(1+r) - C_0)^{-\gamma}]^{-\frac{1}{\gamma}}$$

The table shows that the maximum percentage error of deviation increases for all modifications (i)-(iii) compared to the baseline model. In particular, the error of deviation significantly increases if agents face higher spreads. However, it is naturally impossible to compare these change quantitatively since we plugged in some arbitrary numbers to mimic the new setting. Different values will produce different errors, but we can safely say that errors of deviation generally increase.

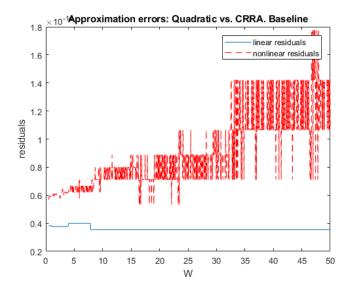

Table 1: Maximum percentage errors of deviation

| | Setting | Example | MPE of deviation |
|-------|---|--------------|------------------|
| | Baseline | | 2.75 |
| (i) | Higher risk aversion γ | γ = 4 | 4.22 |
| (ii) | Lower probability p | p = 0.20 | 3.55 |
| (iii) | Higher mean-preserving interest rate spread | +0.40 | 19.17 |
